## LIGHT TRAP CATCHES OF LEPIDOPTERA IN TWO CENTRAL APPALACHIAN FORESTS

LINDA BUTLER, VICKI KONDO, AND JOHN STRAZANAC

Division of Plant and Soil Sciences, West Virginia University, Morgantown, WV 26506-6108, U.S.A. (e-mail: lbutler@wvu.edu)

**Abstract.**—On 15 sampling dates from May through mid-August 1995 and 1996, 12-watt blacklight traps were operated simultaneously in 18, 200-ha plots, 9 plots each in the George Washington (GWNF) and Monongahela National Forests (MNF) in Virginia and West Virginia, respectively. A total of 438 species of Lepidoptera in 13 selected families was identified including 222 noctuids, 127 geometrids, 27 notodontids, 26 arctiids, 10 sphingids and 9 saturniids. For both years, 334 species were shared by both forests; 45 species were collected only in the GWNF and 59 species were collected only in the MNF. Moth collections totaled 135,271 specimens and varied by forest and year. Variation may have been related to differences in vegetational makeup between the forests and differences in rainfall and temperature between the two years. The GWNF is a warmer, more xeric oak/pine forest while the MNF is relatively more mesic, mixed hardwood forest at a higher elevation. For both forests combined, the most abundant light-trapped species were, in decreasing abundance, *Acronicta ovata* Grote (Noctuidae), *Idia rotundalis* (Walker) (Noctuidae), *Hypoprepia fucosa* Hübner (Arctiidae), *Idia aemula* Hübner (Noctuidae), *Polygrammate hebracicum* Hübner (Noctuidae), *Hydrelia inornata* Hulst (Noctuidae), *Itame pustularia* (Guenée) (Geometridae), *Spilosoma congrua* Walker (Arctiidae), *Lambdina fervidaria* (Hübner) (Geometridae), and *Halysidota tessellaris* (J. E. Smith) (Arctiidae).

**Key Words:** Lepidoptera, blacklight trap, West Virginia, Virginia

Communities of adult Lepidoptera have been the subject of numerous studies in recent years. Lepidoptera are considered to be of high conservation value (Magurran 1985) and frequently serve as “flagship taxa” in biodiversity studies (Lawton et al. 1998). Moths have been used as indicator organisms for monitoring changes in tropical (Holloway 1984) and temperate zones (Magurran 1985).

In North America, blacklight trapping of moths has been conducted in several locations for a number of purposes. For example, Rings et al. (1987) and Moulding and Madenjian (1979) conducted surveys in the

same forests for several years to determine composition of the Lepidoptera community. Use of light traps in evaluation of sampling methods for biodiversity studies was conducted by Butler et al. (1999), Thomas (1996), and Thomas and Thomas (1994). Studies to determine Lepidoptera baseline composition before forest disturbance by outbreak defoliator species or application of insecticides for forest pest suppression have included those of Butler and Kondo (1991) and Grimble et al. (1992). Light trapping of moths has also served to evaluate nontarget impact of forest-applied insecticides (Butler and Kondo 1993, Butler et al. 1995, Sample et al. 1996).

In 1994, we began a study of the impact of the biological spray, *Bacillus thuringiensis* var. *kurstaki* (*Btk*), and defoliation by gypsy moth (*Lymantria dispar* L.) on non-target arthropods in large plots in adjacent national forests in the central Appalachians. Because *Btk* targets caterpillars (Boberschmidt et al. 1989), an emphasis of this study has been Lepidoptera. Our study dealt with moths from 13 selected families: Drepanidae, Thyatiridae, Geometridae, Epiplemidae, Mimallonidae, Apatelodidae, Lasiocampidae, Saturniidae, Sphingidae, Notoodontidae, Arctiidae, Lymantriidae, and Noctuidae. Pretreatment sampling of adult moths was conducted in 1995 and 1996. Comparisons were made of number of species and abundance between the two years and between the two forests. Here we present the results of the pretreatment portion of that study. Other papers in this series present results of larval sampling by foliage pruning and canvas bands. A final paper will present species diversity indices and accumulation curves for the lepidopteran community.

#### MATERIALS AND METHODS

In 1994, 18 200-ha study plots were designated and flagged in gypsy moth-susceptible, oak-dominated forests. Plots 1 through 9 are located primarily on the eastern slope of Great North Mountain in the Deerfield Ranger District of the George Washington National Forest (GWNF) in Augusta County, Virginia (centered at  $38^{\circ}07'30''N$ ,  $79^{\circ}22'30''W$ ). The GWNF plots are approximately 50 km east of the MNF plots. Maps of the study sites are given in Butler and Strazanac (2000 a,b). The GWNF plots represent a relatively xeric forest of mixed oak and pine with a range in elevation of 586 m to 781 m. Plots 10 through 18 are located in the Monongahela National Forest (MNF) in Pocahontas County, West Virginia (plots 10–15 centered at  $38^{\circ}22'30''N$ ,  $79^{\circ}52'30''W$ , plots 16–18 centered at  $38^{\circ}15'N$ ,  $80^{\circ}00'W$ ). Plots 10 through 12 are in the southern Greenbrier

Ranger District on Chestnut Ridge (Paddy Knob North); plots 13 through 18 are in the Marlinton Ranger District with plots 13 through 15 near Sugar Camp Run (Paddy Knob South); and plots 16 through 18 on Marlin Mountain. The MNF plots represent a relatively more mesic forest with a range of elevation of 860 m to 1,070 m.

Basal area of major tree species was measured at 28 randomly selected points within a central 30-ha core subplot within each of the 18 plots. Basal area was estimated using a 10 basal area factor (BAF) Cruz-all (Jim-Gem; Forestry Suppliers, Inc.; Jackson, MS).

On 20 June 1995, rain gauges and maximum/minimum thermometers were installed in all plots. Additional weather data were obtained from the N.O.A.A. weather stations closest to the plots.

A 12-watt blacklight trap (BioQuip Products, Gardena, CA) powered by a 12-volt battery was operated within the 30-ha core subplot in each of the 18 study plots on Monday night of each week from early May through mid-August (8 May through 14 August 1995; 6 May through 12 August, 1996) to give 15 samples per plot per year. Each trap was equipped with a photoelectric eye to facilitate automatic dusk to dawn operation. Insects were killed by Vapona™ insecticide strips placed in the light trap bucket. Each trap was suspended about 1.5 m above the ground between two trees, approximately 2 m apart. Care was taken in trap placement to select locations that appeared similar among plots with regard to vegetation density and composition (within the limitations of core plot differences), and to avoid sites where traps would be shielded by tree limbs.

Trapped insects were collected each Tuesday morning, placed in plastic cartons between layers of Kimwipes™, held in coolers, returned to the laboratory, and stored in a freezer. Moths were identified to species by Kondo and Butler and counts made by week for each species. Species are named after the checklist given by Hodges

et al. (1983). Voucher specimens from the study are deposited in the WVU Arthropod Collection.

## RESULTS

A total of 438 species of moths in 13 families was collected by blacklight trap in 1995 and 1996 (Table 1). Fifty-one percent of the species were Noctuidae (222 species), 29 percent were Geometridae (127 species), 6 percent each were Notodontidae (27 species) and Arctiidae (26 species), and 2 percent each were Sphingidae (10 species) and Saturniidae (9 species). These percentages of species per family are similar to those given in Hedges' (1983) checklist where these families represented 58 percent, 28 percent, 3 percent, 5 percent 2.5 percent, and 1.4 percent respectively. The remaining 7 families were represented by 5 or fewer species. Over both years, 379 and 393 species were collected from the GWNF and the MNF, respectively. Collections for 1995 totaled 339 and 334 species for the GWNF and the MNF, respectively, while 1996 numbers were 313 and 338 species. For both years, 334 species were shared by both forests; 45 species were represented only in the GWNF, and 59 species were collected only in the MNF (Table 1).

During both years of the study and in both forests, a total of 135,271 moths were collected and identified (Table 1). The highest abundance of moths was collected on the MNF in 1996 (39,069); followed by GWNF, 1995 (35,745); MNF, 1995 (35,593); and GWNF, 1996 (24,864). The family with the highest abundance for both forests and both years was Noctuidae with 65,115 individuals followed by Geometridae (37,744), Arctiidae (18,279), Notodontidae (9,839), Lasiocampidae (1,400), Saturniidae (1,286), Sphingidae (856), and Lymantriidae (474). All other families were represented by fewer than 100 individuals.

Over both years and both forests the most abundant species listed in order of decreasing abundance were *Acronicta ovata* Grote (Noctuidae), *Idia rotundalis* (Walker) (Noctuidae), *Hypoprepia fucosa* Hübner (Arctiidae), *Idia aemula* Hübner (Noctuidae), *Polygrammate hebraicum* Hübner (Noctuidae), *Hydrelia inornata* Hulst (Geometridae), *Itame pustularia* (Guenée) (Geometridae), *Spilosoma congrua* Walker (Arctiidae), *Lambdina fervidaria* (Hübner) (Geometridae), *Halysidota tessellaris* (J.E. Smith) (Arctiidae), *Acronicta increta* Morrison (Noctuidae), *Acronicta haesitata* (Grote) (Noctuidae), *Clemensia albata* Packard (Arctiidae), *Probole alienaria* (Herrich-Schäffer) (Geometridae), *Hypagyrtis unipunctata* (Haworth) (Geometridae), *Nadata gibbosa* (J.E. Smith) (Noctuidae), *Peridea angulosa* (J.E. Smith) (Noctuidae), *Eupithecia matheri* Rindge (Geometridae), *Anorthodes tarda* Guenée (Noctuidae), and *Semiothisa bisignata* (Walker) (Geometridae) (Table 1).

Among the 20 more abundant species, 7 were notably more abundant in the MNF (*A. ovata*, *I. rotundalis*, *H. inornata*, *S. congrua*, *L. fervidaria*, *P. alienaria*, and *A. tarda*); 4 were notably more abundant in the GWNF (*I. aemula*, *P. hebraicum*, *I. pustularia* and *S. bisignata*). The remaining 9 species were in similar abundance in both forests (Table 1). Among the 438 species identified during this study (Table 1), 35 were represented over both years by a single individual.

During 1995 and 1996 combined, 45 moth species were trapped only in the GWNF and 59 species were trapped only in the MNF. Of those 104 species, half (53 species) were represented by only one or two individuals (Table 1). Several species trapped only in the GWNF in some abundance were the geometrid, *Lytrosis permagnaria* (Pack); the saturniids, *Eacles imperialis* (Drury) and *Anisota stigma* (F.); the arctiids, *Crambidia cephalica* (Grote and Robinson); and the noctuids *Catocala fribilis* Grote and *C. similis* Edwards. Among species unique to the MNF were the geometrids *Itame evagaria* (Hulst), *Aethalura intertexta* (Walker), *Epirrhoë alternata* (Müller), and *Heterophleps refusaria*

## PROCEEDINGS OF THE ENTOMOLOGICAL SOCIETY OF WASHINGTON

Table 1. Species of Lepidoptera and their abundance collected by light traps on the George Washington (GWNF) and Monongahela (MNF) national forests, 1995 and 1996. Ranks and flight ranges are included.

Table 2. Temperature and rainfall measurements from May through August, 1995 and 1996 for the GWNF and the MNF.

Year	Forest	Temperature (°C)		
		Av. Low	Av. High	Rainfall (cm)
1995	GWNF	16.8	28.5	21.8
	MNF	13.9	23.8	16.8
1996	GWNF	12.0	27.1	39.1
	MNF	10.0	24.4	49.3

(Walker); the notodontid *Peridea ferruginea* (Packard); and the noctuids *Lithacodia concinnimacula* (Guenée), *Phlogophora iris* Guenée, *Lithophane innominata* (Smith), *Polia nimbosa* Guenée, *Lacinipolia olivacea* (Morrison), and *Pseudoorthodes vecors* (Guenée).

Temperature and rainfall recorded over a 30-year period (1961–1990) at NOAA stations near our plots indicate annual maximum temperatures are higher in the GWNF (17.8°C) than the MNF (16.4°C) and median annual rainfall is lower in the GWNF (96.8 cm) than the MNF (125.5 cm) (Owenby and Ezell 1992). During our current study, average low and high temperatures were higher in the GWNF than the MNF for both years (Table 2). In 1995, total rainfall recorded in our plots from May through August was higher in the GWNF than the MNF. Most of that rain fell during one large storm event in the GWNF in early June 1995. The 1996 rainfall was higher in the MNF than the GWNF, thus being more typical of the 30-year trend.

No clear trend in lepidopteran abundance was seen between the two years of the study. Higher overall abundance was collected in 1995 (71,336), the warmer, drier year (Table 1). The difference between years for the GWNF was considerable with 51% higher abundance of moths trapped in 1995. For the MNF, the reverse occurred with the abundance in 1996 being 9% higher than in 1995. Several of the more abundant species showed a notable shift in abundance between the two years.

The mean basal area contributed by dom-

Table 3. Abundance of major tree groups as indicated by mean basal areas for the GWNF and the MNF. Range and standard error are given.

Tree	GWNF			MNF		
	Mean	Range	SE	Mean	Range	SE
<i>Acer</i> spp.	0.52	0.08–0.90	0.21	2.70	0.55–8.16	0.56
<i>Carya</i> spp.	1.13	0.74–2.05	0.47	2.48	0.66–6.31	0.63
<i>Pinus</i> spp.	4.98	0.90–10.16	0.99	2.77	0.0–8.44	0.56
<i>Q. alba</i>	0.78	0.0–1.64	0.28	3.41	0.33–7.95	0.61

<i>Q. (Erythrobalanus)</i>	6.37	5.33–8.44	0.94	4.45	1.97–8.44	0.81
Other	1.08	0.25–1.97	0.42	2.78	0.74–5.49	0.76

inant tree species including the host species emphasized in our study is given in Table 3. Basal areas of hickories, maples, white oak, and other species, were higher in the MNF while basal areas of chestnut oak, red oaks (subgenus *Erythrobalanus* spp.), and pines were higher in the GWNF. The higher composition of red oak/pine in the GWNF is indicative of more xeric conditions. The mean basal area represented by "other species" on our plots was 61% higher in the MNF than the GWNF, indicating an overall greater diversity in species composition of woody vegetation. Included in the "other" category in the MNF were black (*Betula lenta* L.) and yellow birch (*B. alleghaniensis* Britt.), black cherry (*Prunus serotina* Ehrh.), choke cherry (*P. virginiana* L.), blackgum (*Nyssa sylvatica* Marsh.), black locust (*Robinia pseudo-acacia* L.), serviceberry (*Amelanchier* spp.), white ash (*Fraxinus americana* L.), and mountain laurel (*Kalmia latifolia* L.). With the exception of blackgum and mountain laurel, these species were not abundant in the GWNF plots.

The abundance of moth species within our two study forests depends on many factors, among them, the availability of larval host plants. Many of the species of moths reflect differences in basal area of host trees in the two forests. For example, the basal area of pine is 44% greater in the GWNF plots in comparison with the MNF plots (Table 3). Among moth species requiring pine as a larval host, we typically see a higher abundance on the GWNF: the geo-

metrids, *Semiothisa minorata* (Packard) and *Nepytia semiclusaria* (Walker); the sphingid, *Lapara coniferarum* (J.E. Smith); and the noctuid *Zale helata* (J.B. Smith). Species with larval hosts of *Prunus* spp. (*Lomographa* spp., *Probole alienaria*, *Paonias* spp.); *Robinia* (*Zale unilineata* (Grote), *Euparthenos nubilis* (Hübner); or *Betula* spp. (*Drepana arcuata* Walker, *Acronicta fragilis* Guenée) were typically more abundant in the MNF where the greater vegetational diversity included these tree species in greater abundance. Species with larval hosts of blackgum (*Allotria elonympha* (Hübner), *Polygrammate hebraicum*) were more abundant in the GWNF where blackgum was 84% more abundant in the core plots.

Abundance of selected moth species (Table 4) was highly variable among the 18 plots, and did not relate clearly to abundance of the preferred larval host plant on the plots. For example, while *Semiothisa minorata* was generally more abundant in the GWNF with the highest basal area of pine (Table 3), the highest abundance was not on plot 9 with the highest basal area of pine (10.16) in the core plot. Instead, the highest abundance was trapped on plot 3, with only half the pine basal area. *Hypoepia fucosa*, larvae of which are lichen feeders, was relatively evenly distributed among the plots. The *Idia* spp. whose larvae of which are litter feeders were abundant on all plots with the exception of plot 10. Plot 10 showed a relatively low abundance of most of the selected species (Table

4) except *Hydrelia inornata*, a maple feeder, and *Hypoprepia fucosa*, the lichen feeder. Plot 10 had a higher basal area of maple than any other tree species emphasized in our study. Much of plot 10 is covered with boulders and rock rubble that is frequently covered with lichens. While the highest count of black cherry in the understory of the core plots occurred on plot 12, the highest catch of the cherry-feeder, *Lomographa vestaliata*, occurred in plot 11. Highest numbers of black locust trees were in core plot 12, corresponding with the highest catch of *Euparthenos nubilis* and relatively high catch of *Zale unilineata*, larvae of which are locust specialists.

Examination of the flight period for the 438 lepidopteran species in this study indicates that some species have broad seasonal ranges while others are more restricted (Table 1). True seasonal ranges are best assessed for those species that were caught in relative abundance. Broad flight periods occur for some univoltine species with unsynchronized eclosion periods such as the notodontid *Heterocampa guttivitta* (Walker), the arctiids *Hypoprepia fucosa* and *Spiilosoma congrua*, and the noctuids *Polia detracta* (Walker) and *Polia latex* (Guenée). Broad flight periods may reflect bivoltine or multivoltine life cycles as, for example, the geometrids *Melanolophia canadaria* (Guenée), *Hagyrtis unipunctata*, *Lomographa vestaliata* (Guenée), and the *Lambdina* spp.; the saturniid, *Dryocampa rubicunda* (F.); the notodontid, *Heterocampa umbrata* Walker; the arctiids, *Clemensia albata*, and *Halysidota tessellaris*; and the noctuids *Idia aemula*, *I. rotundalis*, and *Zale minerea* (Guenée). Examples of species with narrow flight periods include the univoltine lasiocampids *Malacosoma* spp. and the arctiid, *Hyphantria cunea* (Drury).

Considerable fluctuation occurred over the 15-week period of each season regarding species numbers and abundance (Figs. 1–2). Generally, the number of species was higher in the GWNF in the spring and higher in the MNF in the summer sampling pe-

riods. No defined peak was noted in species numbers; about 125 species per week were trapped from late May to August. Weekly abundance was generally lowest in the spring sampling periods and highest in July and early August. The highest abundance over the two year period was taken in the MNF on 9 July 1996. Lowest richness and abundance occurred in both forests on the nights of 13 June 1995 and 14 May 1996. While minimum temperatures were not unseasonably low on 13 June (13°C), it was the night of the full moon with 0.999 percent illumination. On 14 May 1996, moon-phase was not a factor (3.2 days before the new moon), but minimum temperature was near 0°C for both forests.

## DISCUSSION

During our two-year study, we collected 438 species of moths, 379 species in the GWNF and 393 species in the MNF. In each forest, blacklight traps were operated at 9 different locations. The numbers of species we collected in this study are consistent with species numbers in hardwood forests in some other studies. Moulding and Madenjian (1979) trapped 410 species of macromoths in a virgin oak forest in New Jersey over a five-year period. Rings et al. (1987) recorded 426 species of macromoths over 9 years in Stark County, Ohio. Work et al. (1998) identified 256 species in 8 red-oak dominant stands in Northern Michigan. Butler and Kondo (1991) trapped 400 species of macromoths with a single 15 watt blacklight trap at one site at Coopers Rock State Forest, WV over a three year period. Butler et al. (1995) trapped 376 species on four small adjacent watersheds at Fernow Experimental Forest, Tucker County, WV over a 5-year period.

Many species were trapped in the current study that were not recorded in the Coopers Rock or Fernow Studies. Several explanations are possible. The vegetation makeup of the current study included significant stands of pine, spruce, or hemlock not present at the earlier study locations. Species

Table 4. Lepidopteran abundance by plot for 1995 and 1996, combined. Host associations of larvae are indicated.

#### Host Associations

<sup>1</sup> Pine.

<sup>2</sup> Black Cherry.

<sup>3</sup> Maple.

<sup>4</sup> Lichen.

<sup>5</sup> Litter.

<sup>6</sup> Black Locust.

<sup>7</sup> Black Gum.

<sup>8</sup> Oak.

in the current study associated with these conifers include the geometrids, *Caripeta angustiorata* Walker, *C. aretaria* (Walker), *Patalene olyzonaria* (Walker), the sphingid, *Lapara coniferarum*, and the noctuids, *Zale squamularis* (Drury), *Z. submediana* (Strand), *Z. duplicata* (Bethune), *Z. helata*, *Z. bethunei* (J.B. Smith), *Panthea acronyctoides* (Walker), and *P. furcilla* (Packard) (Covell 1984; Forbes 1948, 1954). Several species in the current study are considered to be uncommon: the geometrids, *Orthofidonia flaviventa* (Hulst), *Lytrosis permagnaria* (Packard), *Caripeta aretaria*, the notodontid *Hyparpax aurora* (J.E. Smith), and the noctuids, *Zanclognatha martha* Barnes, *Zale squamularis*, *Z. submediana*, *Z. bethunei*, *Catocala connubialis*, Guenée, *Cerma cora* Hübner, *Acronicta tritona* (Hübner), *A. spinigera* Guenée, *Oligia bridghami* (Grote and Robinson), *Homohadena infixa* (Walker), and *Sideridis congermana* (Morrison)

(Covell 1984; Forbes 1948, 1954; Rings et al. 1992).

Because our light trapping period extended only for a 15-week period in May, June, July, and August, moth species that fly before or after that time were not collected. Species in this category that have been collected as larvae in our plots (Butler and Strazanac 2000a,b) include the geometrids *Alsophila pometaria* (Harris), *Phigalia denticulata* Hulst, *P. strigataria* (Minot), *Eriannis tiliaria* (Harris), *Lambdina fiscellaria* (Guenée), and the noctuids, *Cosmia calami* (Harvey), *Lithophane quequera* Grote, *L. grotei* Riley, *Eupsilia* n. sp., *E. morrisoni* (Grote), *Xystopeplus rufago* (Hübner), *Eutolype rolandi* Grote, *Copipanolis styracis* (Guenée), *Orthosia hibisci* (Guenée), and *Himella intractata* (Morrison).

Several groups were not fully identified. It is likely that additional species of *Eupithecia* (Geometridae) are present in our

Table 4. Extended.

samples. The arctiid *Holomelina opella* (Grote) included some *H. nigricans* Reakirt. The lymantriid *Dasychira* spp. includes *D. dorsipennata* (Barnes and McDunnough), *D. obliquata* Grote and Robinson, *D. basiflava* (Packard), and *D. plagiata* (Walker).

*Dasychira* specimens in the light traps were frequently rubbed leaving the pattern difficult to distinguish. Most of these species are highly variable in wing pattern and lack distinctive genitalia (Ferguson 1978).

Among the moth species collected exclu-

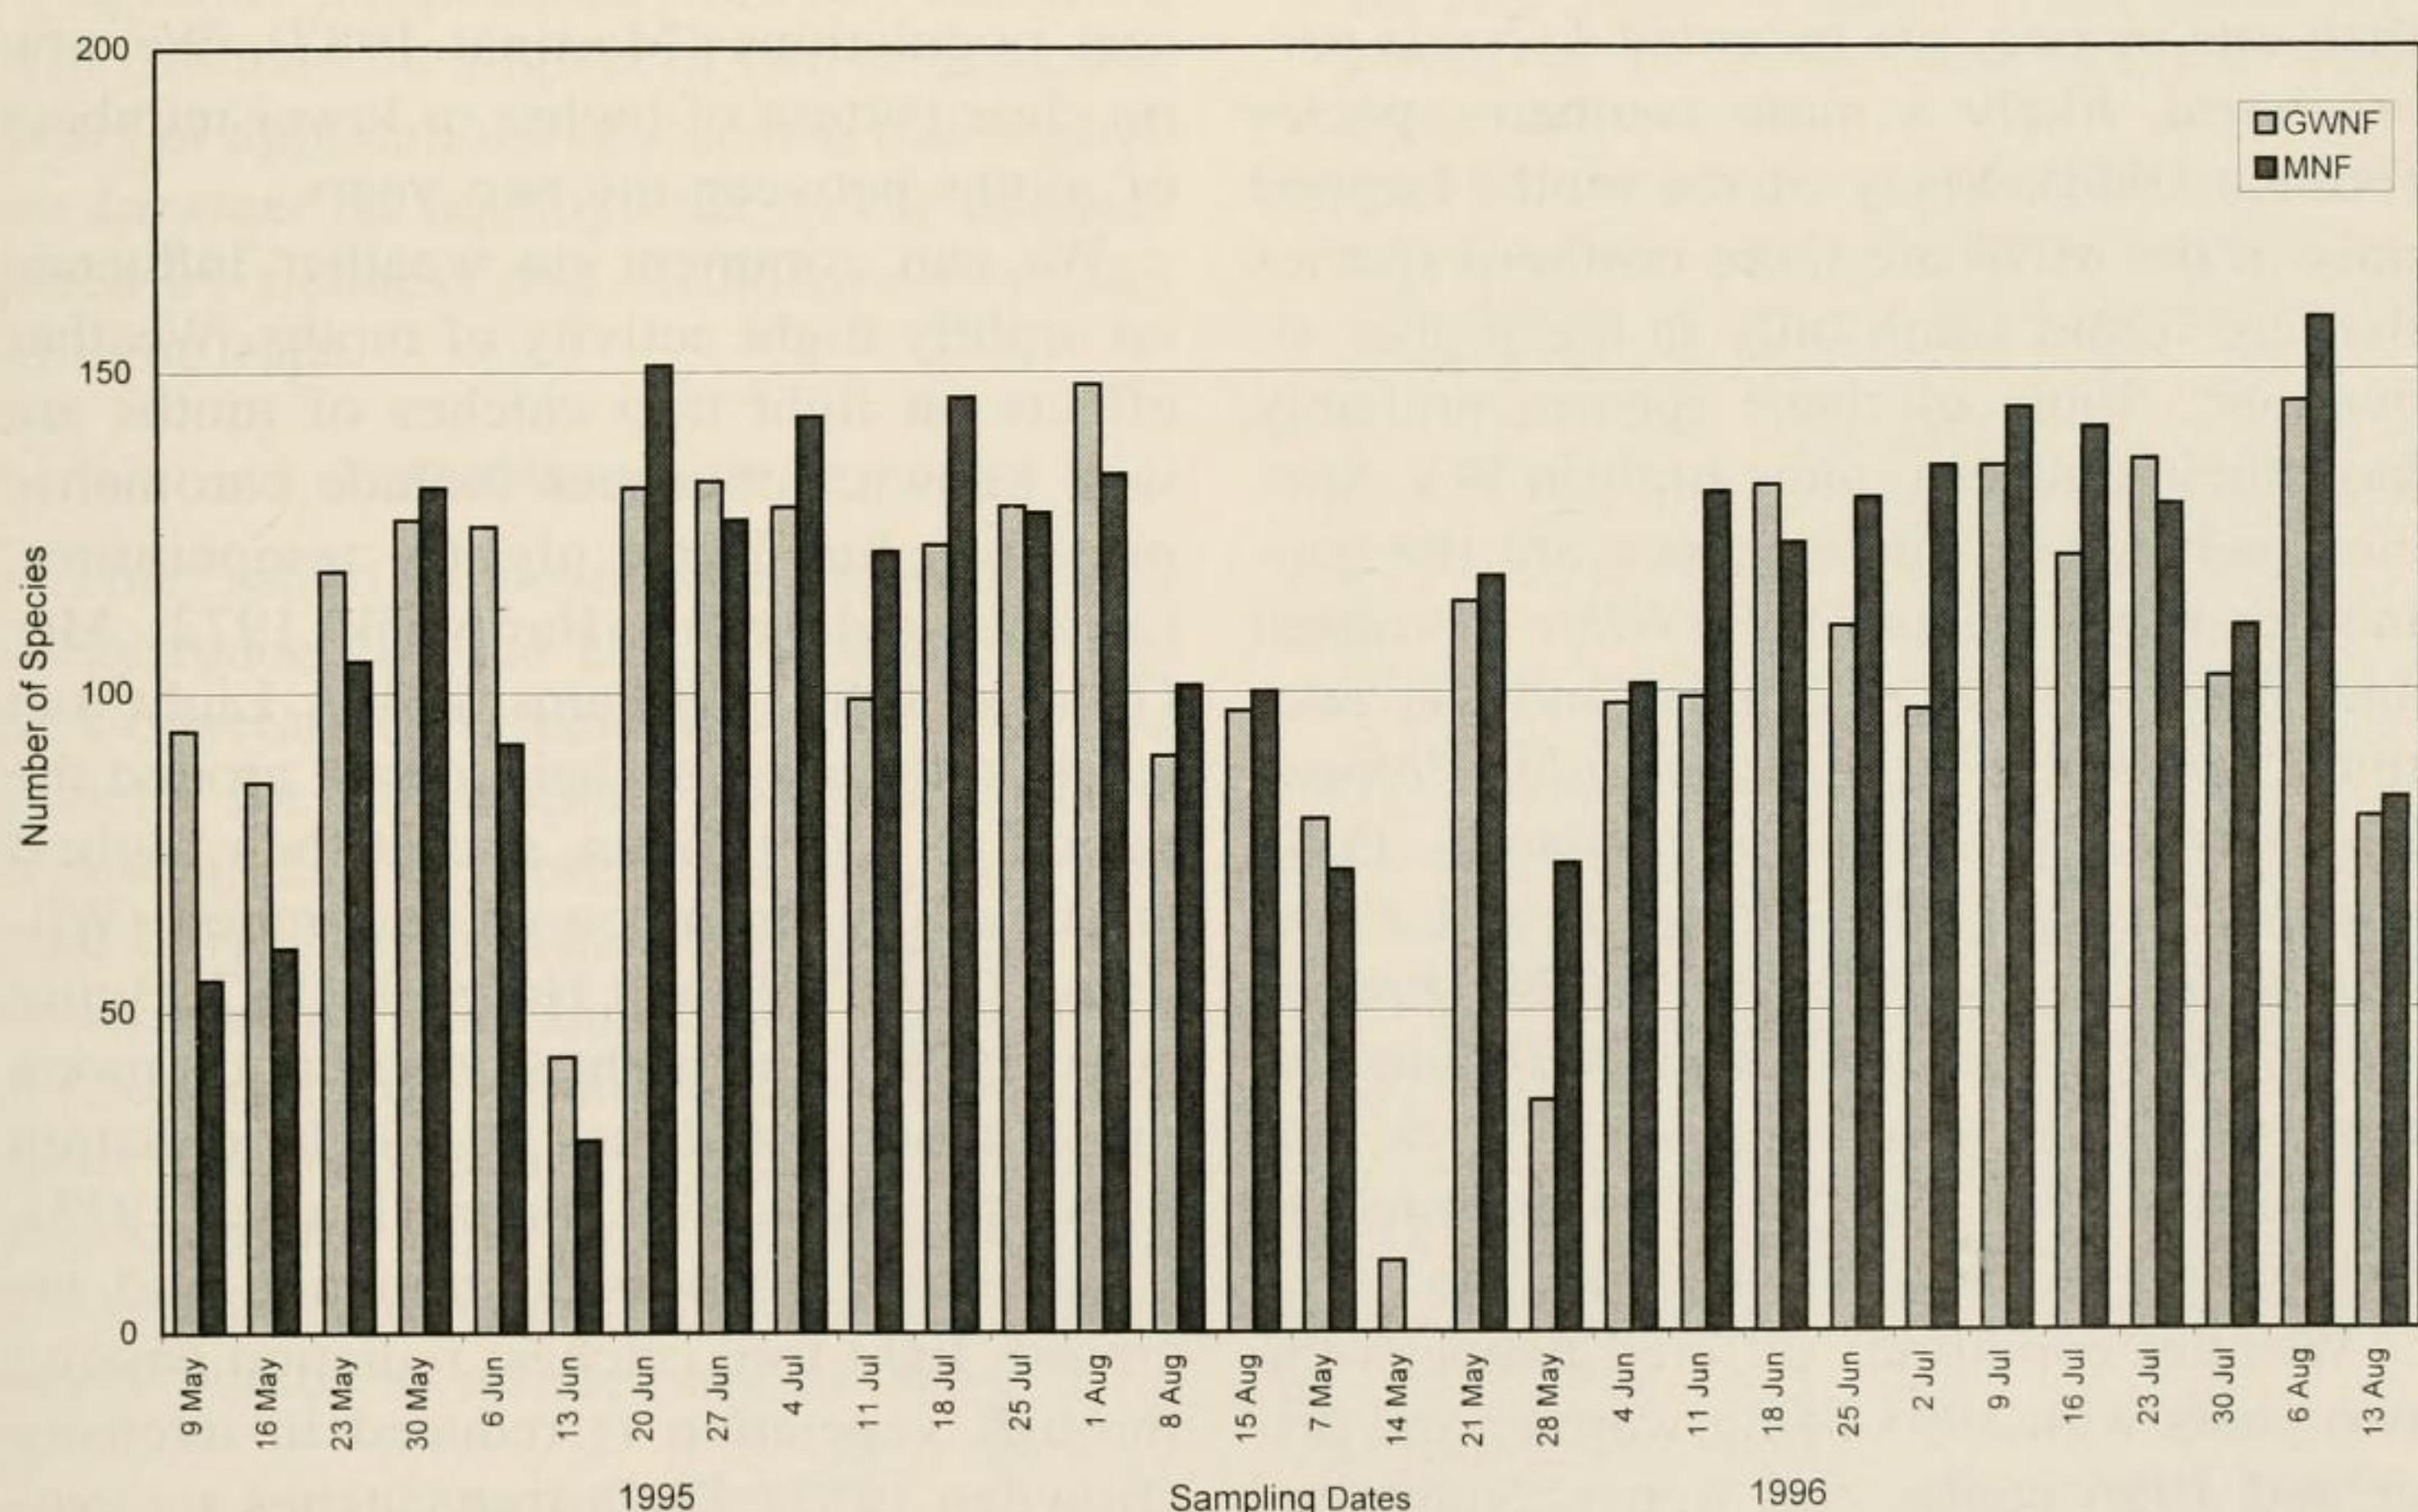

Fig. 1. Lepidopteran species numbers over 15 week sampling periods during 1995 and 1996 in the George Washington (GWNF) and (MNF) Monongahela national forests.

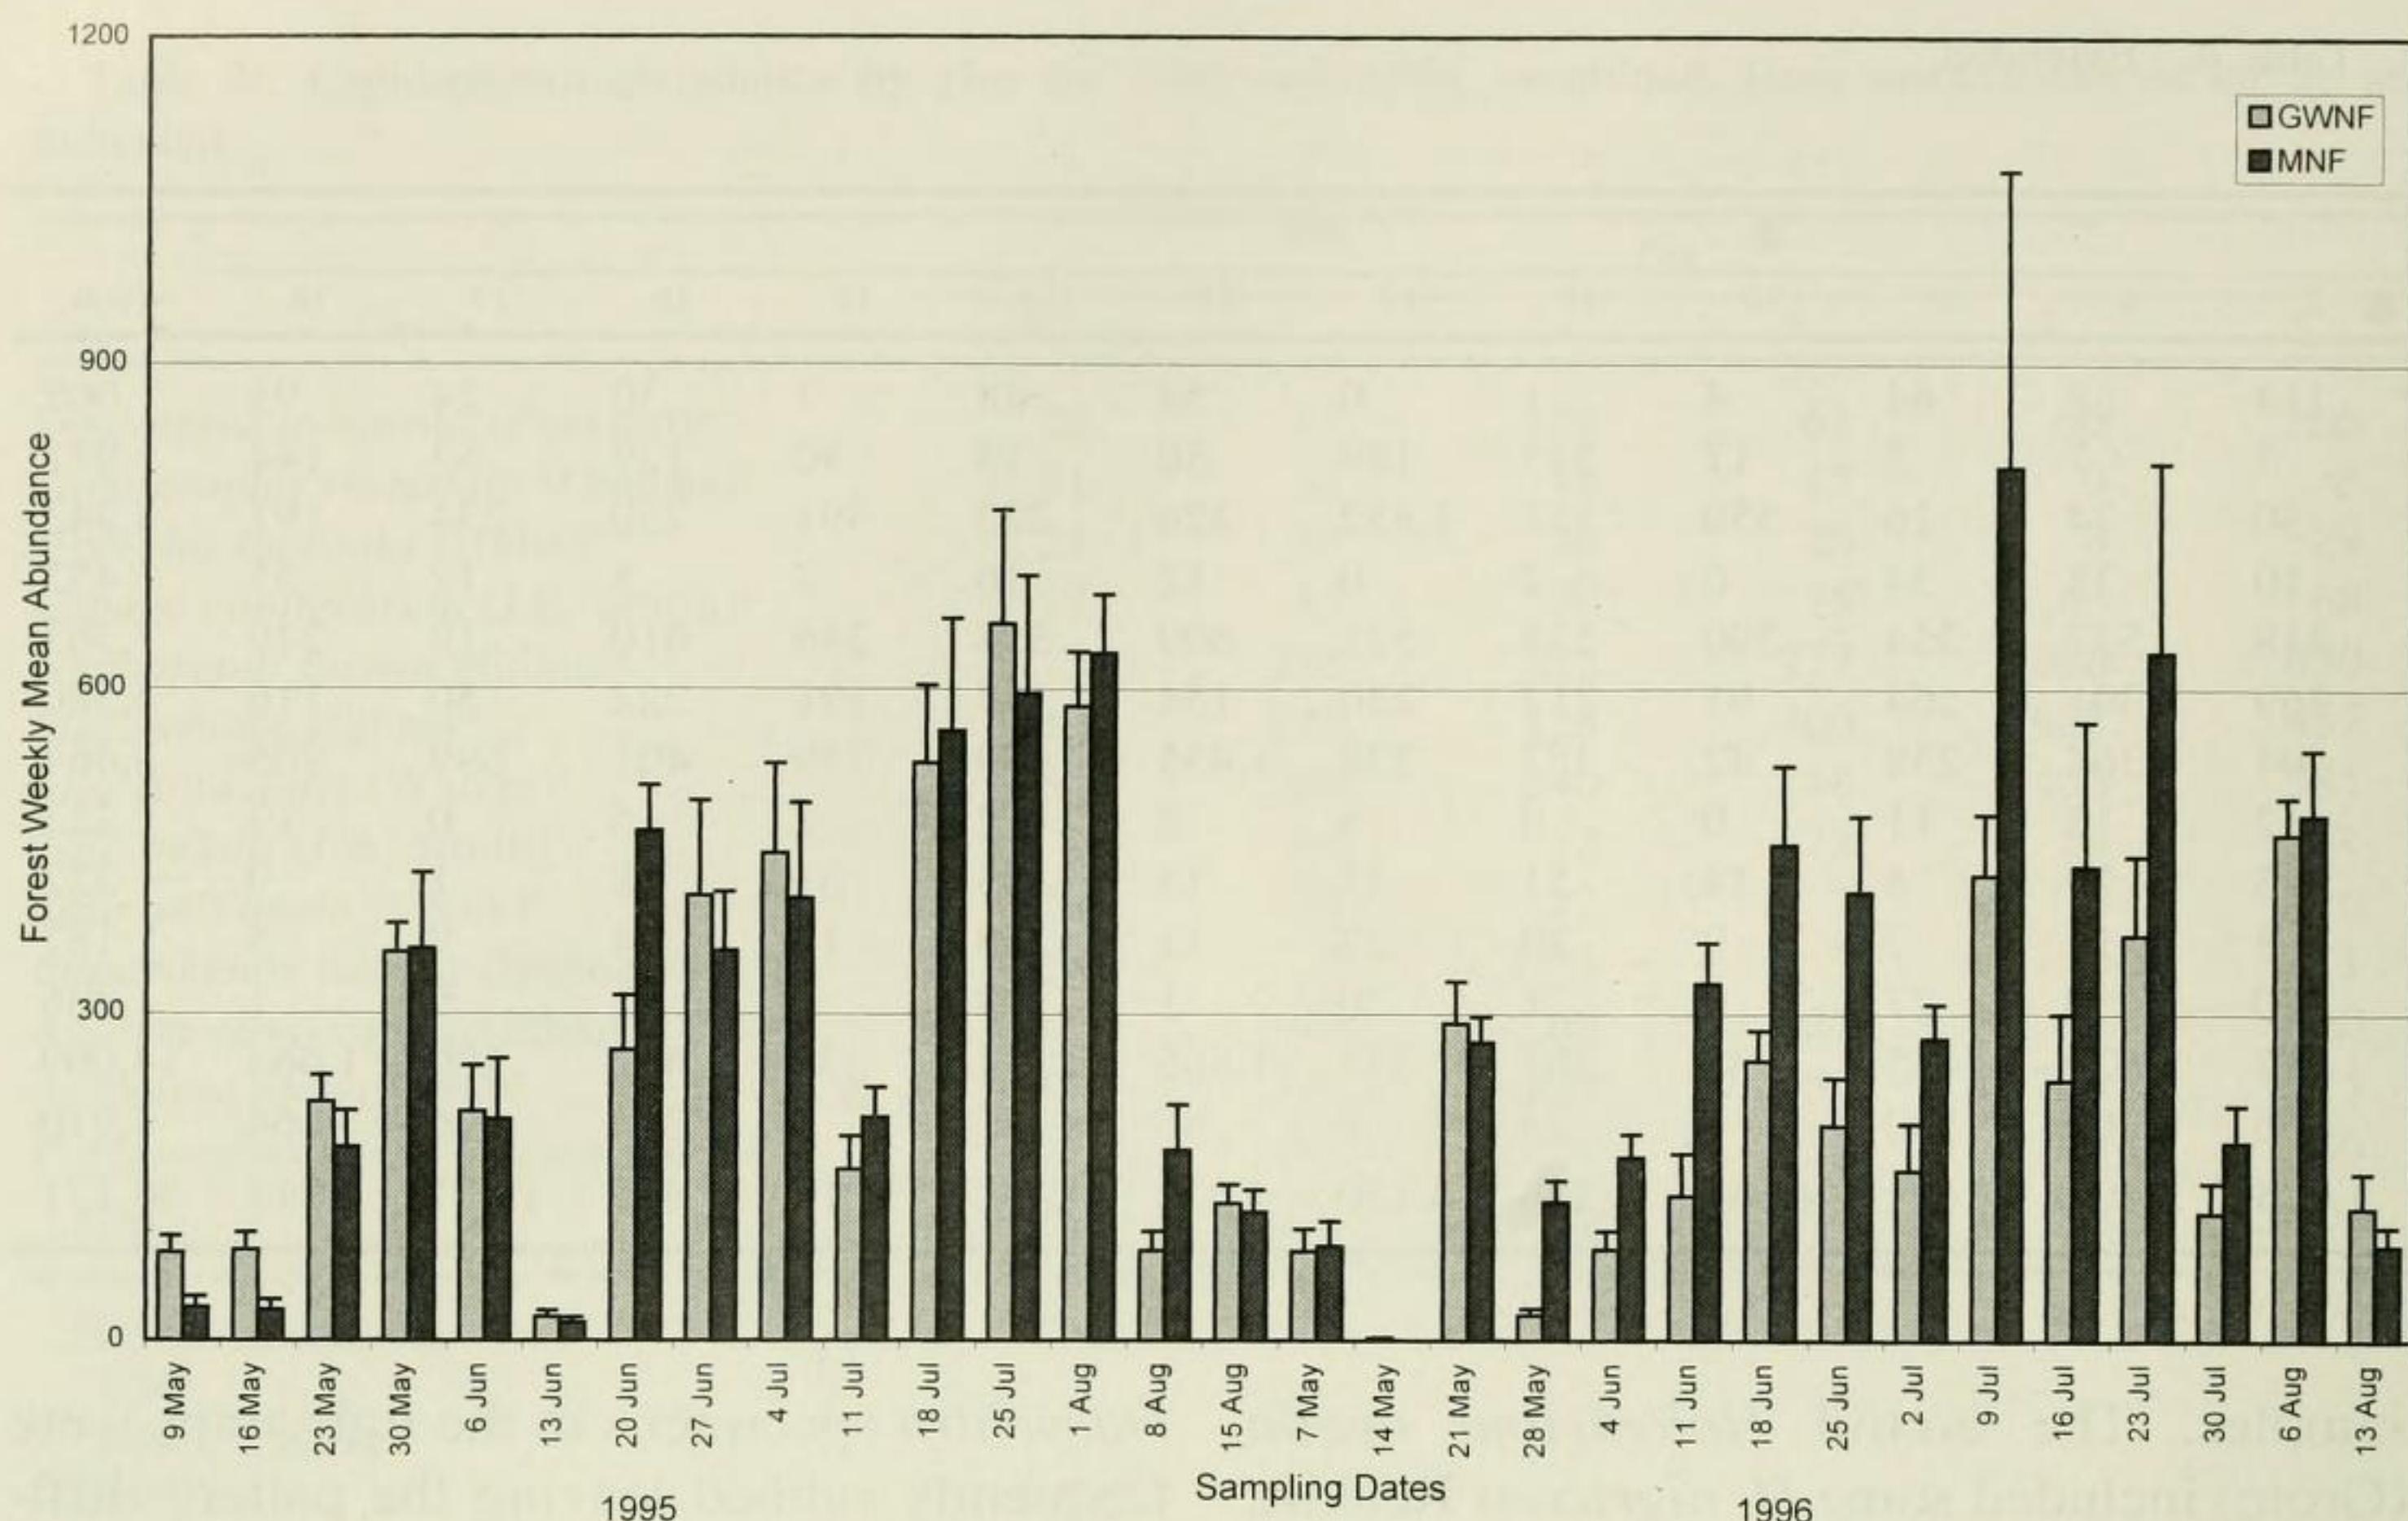

Fig. 2. Lepidopteran weekly mean abundance over 15 week sampling periods during 1995 and 1996 in the George Washington (GWNF) and (MNF) Monongahela national forests.

sively in the GWNF in numbers greater than one or two, we recorded *Lytrosis permagnaria*, likely a more southern species (Forbes 1948). Many of the moths trapped only in the MNF are more northern species that are found south only in the higher elevations. Some of these species probably have their southern range limit in WV. Species included in this category are the geometrids *Itame evagaria*, *Epirrhoe alternata*, and *Heterophleps refusaria*; and the noctuids *Lithacodia concinnimacula*, *Phlogophora iris*, *Lithophane innominata*, *Polia nimboosa*, *Lacinipolia olivacea*, and *Pseudorthodes vecors* (Covell 1984; Forbes 1948, 1954). The geometrid, *Aethalura intertexta* (Walker) is considered to be uncommon (Covell 1984), but we recorded 30 individuals in the MNF in two years.

Weather conditions differed between the two years with 1995 being warmer and drier and 1996 cooler and wetter. Numerous studies have shown direct and indirect effects of weather trends and atypical cata-

strophic temperature and rain events on insect populations (Martinat 1987). We saw no clear pattern of higher or lower numbers of moths between the two years.

We can comment on weather influence on nightly flight activity of moths. Weather effects on light trap catches of moths are well known. Influences include barometric pressure, humidity, nightly temperature, rainfall, and wind (Hardwick 1972, McGeachie 1989, Williams 1940). Light-trap catches are often at their lowest around the period of a full moon, and at their highest at periods of no moon or new moon (Williams 1936, Yela and Holyoak 1997, Butler et al. 1999). The night sky without a moon gives about 140 times less light radiation than one with a full moon (Kuiper 1938). Cloud cover reduces illumination and increases light-trap catches; radiation passing through vegetation is reduced in intensity (Bowden 1982). Light-trap catches are generally higher on warm, humid nights with no moonlight (McGeachie 1989). In sam-

pling of noctuid moths by light trap in Spain, temperature was the dominant environmental factor influencing trapped moth numbers (Yela and Holyoak 1997). Average light trap catch varied 6- to 9-fold because of changes in temperature. Moonlight and cloud cover were second in influence and caused light trap catches to vary by 2-fold (Yela and Holyoak 1997). In our current study, nights of reduced sample size were influenced by full moon or unseasonably low temperatures (Butler et al. 1999).

During this study, sampling was restricted to a 15-week period, May through mid-August. While 438 species indicate relatively high diversity, increasing the length of the sampling season and sampling for additional years would produce records for many additional species. Other factors also limit species numbers as sampled by blacklight trap. All nocturnal lepidopterans do not respond equally well, or at all, to wavelengths emitted by blacklight traps; some species do not disperse far from the site of the larval host plants (Grimble et al. 1992).

In future publications from this study, we will evaluate the impact of two consecutive years of applications of *Bacillus thuringiensis kurstaki* on lepidopteran larvae as measured by richness and abundance of moths in light traps.

#### ACKNOWLEDGMENTS

This report represents a portion of a study funded by the USDA Forest Service as Cooperative Agreement 42-793; we are grateful for that support. We thank Richard Reardon, USDA Forest Service, and our staff of research assistants and graduate and undergraduate assistants. We particularly acknowledge the contribution of Deborah Blue. This manuscript is approved for publication by the Director of the West Virginia University Agriculture and Forestry Experiment Station as article number 2733.
